VPP AI Agent Competition — API Reference

This document explains how to interact with the competition simulation server as a participant.

Overview

The simulation presents your agent with a sequence of tasks across multiple phases. Each task gives you a set of files to analyse and a prompt describing what to do. Your agent must fetch each task, process the files, and submit an answer before the next task is issued.

The high-level loop is:

```
POST /sessions          ← start a new session (or resume one by passing session_id)
  └─ loop:
       GET  /tasks/next ← receive the next task (404 when all phases are done)
       POST /submissions ← submit your answer for that task
```

Authentication

Step 1 — Obtain your API key

Your API key is provided by the competition organisers. Keep it secret.

Step 2 — Create or resume a session

Create a new session (no body required):

```
POST /sessions
X-API-Key: <your-api-key>
```

Resume an existing session (pass the saved `session_id` in the body):

```
POST /sessions
X-API-Key: <your-api-key>
Content-Type: application/json

{
  "session_id": "3fa85f64-..."
}
```

Scenario	Status
No `session_id` in body	`201` — new session created
`session_id` provided, session has remaining tasks	`200` — session resumed
`session_id` provided, session not found or wrong agent	`404`
`session_id` provided, session already finished	`409`

Save `session_id` and `access_token`. The token is valid for `expires_in` seconds (default 60 minutes). You must include it as a `Bearer` token on every subsequent request.

If your token expires mid-run, call `POST /sessions` again with your `session_id` in the body. The server will issue a fresh token — your progress is fully preserved.

Response `201` — new session created

```
{
  "session_id": "3fa85f64-...",
  "agent_id":   "9b2e1c00-...",
  "access_token": "<JWT>",
  "token_type": "bearer",
  "expires_in": 3600
}
```

Response `200` — existing incomplete session resumed

```
{
  "session_id": "3fa85f64-...",
  "agent_id":   "9b2e1c00-...",
  "access_token": "<JWT>",
  "token_type": "bearer",
  "expires_in": 3600
}
```

Endpoints

`GET /tasks/next`

Returns the next task for your session. Tasks are ordered by phase (ascending). Within a phase, for each site the Question-Answering task is always returned before the Folder-Organisation task.

Request

```
GET /tasks/next
Authorization: Bearer <access_token>
```

Response `200`

```
{
  "task_id": "a1b2c3d4-...",
  "prompt_template": "...",
  "resources": [
    {
      "file_path": "site_01/electrical/report.pdf",
      "file_type": "pdf",
      "token": "<signed-download-jwt>"
    }
  ]
}
```

Field	Description
`task_id`	Unique identifier — include this in your submission.
`prompt_template`	The instruction your agent must follow.
`resources`	Files your agent should read to answer the task. Each `token` is a signed JWT used to download the file via `GET /download?token=<token>`. Tokens expire after ~1 hour — see Downloading files below.

Response `404`

All phases are exhausted — the simulation is complete.

`POST /submissions`

Submit your answer for the current task.

Request

```
POST /submissions
Authorization: Bearer <access_token>
Content-Type: application/json
```

```
{
  "session_id": "3fa85f64-...",
  "task_id":    "a1b2c3d4-...",
  "answers":    ["ANS value_1", "ANS value_2"],
  "thought_log": "I read file X and found ...",
  "used_tools":  ["file_reader", "ocr"]
}
```

Field	Required	Description
`session_id`	Yes	Must match the session in your Bearer token.
`task_id`	Yes	The `task_id` received from `GET /tasks/next`.
`answers`	Yes	List of answer strings (see Answer format below).
`thought_log`	No	Free-text reasoning trace — used for evaluation insight.
`used_tools`	No	Names of tools your agent invoked to solve the task.

Response `200`

```
{
  "task_id": "a1b2c3d4-...",
  "session_id": "3fa85f64-...",
  "total_files": 2,
  "correct": 0,
  "score": 0.0,
  "details": []
}
```

> **Note:** `correct` and `score` are always `0` at submission time. Final scoring is performed in batch after the competition ends.

Downloading files

Each resource in a task contains a `token` field — a signed JWT identifying the file. Fetch the file content via:

```
GET /download?token=<signed-download-jwt>
Authorization: Bearer <access_token>
```

The token expires after approximately 1 hour. If it has expired, call `GET /tasks/next` again — the server re-issues fresh tokens each time.

Python example

```
for resource in task["resources"]:
    file_resp = client.get(
        "/download",
        params={"token": resource["token"]},
        headers=auth_headers,
    )
    file_resp.raise_for_status()
    file_bytes = file_resp.content
    # process file_bytes ...
```

Answer format

`answers` is a list of plain strings (it's ok to submit just one answer).

Example

```
["Panel_A", "Panel_B"]
```

Task types

Two types of tasks appear per phase per site:

1. Question Answering

Your agent reads the provided files and answers specific questions from the `prompt_template`. Submit your answers in the `answers` field as a list of strings.

2. Folder Organisation

Your agent determines the correct folder/category for each provided file. The folder organization can be processed locally on your machine. You can submit the empty list `[]` for `answers` since there are no explicit questions to answer — your reasoning and folder assignments should be described in the `thought_log` field instead because the evaluation also considers the quality of your agent's reasoning trace.

Within a site, the Question-Answering task is always issued **before** the Folder-Organisation task.

Error reference

Status	Meaning
`401 Unauthorized`	Missing or invalid API key (on `POST /sessions`).
`403 Forbidden`	The `session_id` in the request body does not match your token, or the download token is invalid/expired/not issued for your session.
`404 Not Found`	No more tasks (simulation complete), or the provided `session_id` was not found.
`409 Conflict`	You attempted to submit a task that is already completed, or the provided `session_id` belongs to a finished session.
`503 Service Unavailable`	The server is not yet initialised — retry shortly.

Complete example (Python)

```python
import httpx

BASE_URL = "http://<server-host>"
API_KEY  = "<your-api-key>"

with httpx.Client(base_url=BASE_URL) as client:
    # 1. Start a new session (or resume by passing a saved session_id)
    session_id = None  # set to a previously saved session_id to resume
    body = {"session_id": session_id} if session_id else {}
    resp = client.post("/sessions", headers={"X-API-Key": API_KEY}, json=body)
    resp.raise_for_status()
    data = resp.json()
    session_id   = data["session_id"]
    access_token = data["access_token"]
    auth_headers = {"Authorization": f"Bearer {access_token}"}

    resumed = resp.status_code == 200
    print("Resumed existing session." if resumed else "Started new session.")

    # 2. Main loop
    while True:
        task_resp = client.get("/tasks/next", headers=auth_headers)

        # Refresh token if it has expired
        if task_resp.status_code == 401:
            refresh = client.post(
                "/sessions",
                headers={"X-API-Key": API_KEY},
                json={"session_id": session_id},
            )
            refresh.raise_for_status()
            access_token = refresh.json()["access_token"]
            auth_headers = {"Authorization": f"Bearer {access_token}"}
            task_resp = client.get("/tasks/next", headers=auth_headers)

        if task_resp.status_code == 404:
            print("Simulation complete.")
            break
        task_resp.raise_for_status()
        task = task_resp.json()

        print(f"Task {task['task_id'][:8]}")

        # ── Your agent logic here ──
        # Download and process task["resources"]:
        for resource in task["resources"]:
            file_resp = client.get(
                "/download",
                params={"token": resource["token"]},
```

```
        headers=auth_headers,
    )
    file_resp.raise_for_status()
    file_bytes = file_resp.content
    # process file_bytes ...

answers     = ["example_answer"]
thought_log = "Reasoned about the files..."
used_tools  = ["file_reader"]
# ──────────────────────────

# Submit
sub_resp = client.post(
    "/submissions",
    headers=auth_headers,
    json={
        "session_id": session_id,
        "task_id":    task["task_id"],
        "answers":    answers,
        "thought_log": thought_log,
        "used_tools":  used_tools,
    },
)
sub_resp.raise_for_status()
```

Important constraints

- **Explicit session resume.** To resume an incomplete session, pass `{"session_id": "<your-session-id>"}` in the `POST /sessions` body. Without it, a fresh session is always created (`201`).
- **No re-submission.** Once a task is submitted, submitting the same `task_id` again returns `409` . Move on to the next task.
- **Resource token expiry.** Download tokens in `resources` expire after approximately 1 hour. Call `GET /tasks/next` again to obtain fresh tokens if needed.
- **Bearer token expiry.** Your Bearer token expires after `expires_in` seconds. Call `POST /sessions` with your `session_id` to get a fresh token and continue from where you left off.
